## ABSTRACT

The Behrens-Fisher problem arises when one seeks to make inferences about the means of two normal populations without assuming the variances are equal. This paper presents a review of fundamental concepts and applications used to address the Behrens-Fisher problem under fiducial, Bayesian, and frequentist approaches. Methods of approximations to the Behrens-Fisher distribution and a simple Bayesian framework for hypothesis testing are also discussed. Finally, a discussion is provided for the use of generalized "p" values in significance testing of hypotheses in the presence of nuisance parameters. It is shown that the generalized "p" value based on a frequentist probability for the Behrens-Fisher problem is numerically the same as those from the fiducial and Bayesian solutions. A table of tests of significance is also included. (Contains 3 tables, 2 figures, and 93 references.)

# On the Behrens-Fisher Problem: A Review

## Abstract

The Behrens-Fisher problem arises when one seeks to make inferences about the means of two normal populations without assuming the variances are equal. This paper presents a review of fundamental concepts and applications used to address the Behrens-Fisher problem under fiducial, Bayesian, and frequentist approaches. Methods of approximations to the Behrens-Fisher distribution and a simple Bayesian framework for hypothesis testing are also discussed. Finally, a discussion is provided for the use of generalized  $p$  values in significance testing of hypotheses in the presence of nuisance parameters. It is shown that the generalized  $p$  value based on a frequentist probability for the Behrens-Fisher problem is numerically the same as those from the fiducial and Bayesian solutions. A table for tests of significance is also included.

*Key words:* Behrens-Fisher problem, two means problem, unequal variances.

## Introduction

A frequently encountered problem in applied statistics is testing the difference between two population means. The Behrens-Fisher problem arises when one seeks to make inferences about the means of two normal populations without assuming either that the variances are equal or that the ratio of variances is known. Under such conditions, Neyman-Pearson (1928, 1933) sampling theory may provide a different solution from those available via either Bayesian theory (e.g., Jeffreys, 1940) or Fisher's (1935, 1939) fiducial theory (Kendall & Stuart, 1979; Lehmann, 1993). Although a number of methods have been proposed for the Behrens-Fisher problem beginning with Behrens (1929) and Fisher (1935), no definitive solutions exist (Robinson, 1982). For reasonably large sample sizes, differences between various extant solutions are generally much less than between these solutions and use of Student's *t* test. When sample sizes are small, however, the three theories may yield different solutions. In the context of Bayesian and fiducial theories, several sets of tables (Fisher & Healy, 1956; Fisher & Yates, 1957; Issacs, Christ, Novick, & Jackson, 1974; Lindley & Scott, 1984; Sukhatme, 1938; Sukhatme, Thawani, Pendharkar, & Natu, 1951) have been presented for the Behrens-Fisher problem. No tables are available, however, for directional hypothesis testing for even numbers of degrees of freedom and small sample sizes.

This paper presents a review of the Behrens-Fisher problem, focusing on fundamental concepts and applications rather than theoretical and philosophical considerations. It begins with expositions of Fisher's fiducial and Jeffreys' Bayesian approaches to the Behrens-Fisher problem. A table is then presented for significance tests which includes cases for even numbers of degrees of freedom and small sample sizes under directional hypothesis testing. Also discussed are methods of approximations of the Behrens-Fisher distribution and a simple Bayesian framework for hypothesis testing (Lindley, 1965). In addition, frequentist approaches (Aspin, 1948; Tsui & Weerahandi, 1989; Welch, 1938, 1947) are discussed. Finally, it is shown that the generalized *p* value (Tsui & Weerahandi, 1989) is numerically the same as those obtained from the fiducial and Bayesian solutions. Examples are presented to illuminate similarities and differences among various methods.

## Formulation of the Problem

We motivate the discussion of the Behrens-Fisher problem with an example taken from Marascuilo and Serlin (1988, p. 229). In this problem, patients in a mental health clinic were given one of two initial treatments:  $n_1 = 4$  patients received a film treatment and  $n_2 = 3$  patients received an interview treatment. Researchers wanted to know whether the patients in the film treatment and the interview treatment differed in the number of times they returned to the clinic for subsequent treatment. The following are the data for this problem:  $x_1 = (x_{11}, \dots, x_{1n_1}) = (8, 10, 12, 15)$ ,  $\bar{x}_1 = 11.25$ ,  $s_1^2 = 8.91667$ ,  $x_2 = (1, 7, 11)$ ,  $\bar{x}_2 = 6.33333$ , and  $s_2^2 = 25.33333$ , where the sample mean and sample variance for  $i = 1, 2$  are defined as

$$\bar{x}_i = \frac{1}{n_i} \sum_{j=1}^{n_i} x_{ij} \quad (1)$$

and

$$s_i^2 = \frac{1}{n_i - 1} \sum_{j=1}^{n_i} (x_{ij} - \bar{x}_i)^2. \quad (2)$$

We assume that the two independent samples,  $x_{1j}$  and  $x_{2j}$ , were drawn from two normal distributions having means  $\mu_1$  and  $\mu_2$  and variances  $\sigma_1^2$  and  $\sigma_2^2$ , respectively. With the assumption of equal variances, that is,  $\sigma_1^2 = \sigma_2^2 = \sigma^2$ , the population variance is estimated by the pooled sample variance,  $s^2 = 15.48333$ , using

$$s^2 = \frac{(n_1 - 1)s_1^2 + (n_2 - 1)s_2^2}{n_1 + n_2 - 2}. \quad (3)$$

The sufficient statistics for  $\mu_1$ ,  $\mu_2$ , and  $\sigma^2$  are  $\bar{x}_1$ ,  $\bar{x}_2$ , and  $s^2$ . Note also that  $\bar{x}_2 - \bar{x}_1$  has a normal distribution with mean  $\delta = \mu_2 - \mu_1$  and variance  $(1/n_1 + 1/n_2)\sigma^2$ . The Student's  $t$  pivotal statistic with  $n_1 + n_2 - 2$  degrees of freedom is

$$t = \frac{\delta - (\bar{x}_2 - \bar{x}_1)}{\sqrt{(1/n_1 + 1/n_2)s^2}} \sim t(n_1 + n_2 - 2). \quad (4)$$

If we denote  $t_{\alpha/2}(\nu)$  as the value for which

$$\Pr\{t > t_{\alpha/2}(\nu)\} = \alpha/2 \quad (5)$$

and also denote

$$\alpha = \Pr\{t < -t_{\alpha/2}(\nu)\} + \Pr\{t > t_{\alpha/2}(\nu)\}, \quad (6)$$

then the  $100(1 - \alpha)\%$  confidence interval for  $\delta$  is

$$\bar{x}_2 - \bar{x}_1 \pm t_{\alpha/2}(n_1 + n_2 - 2) \sqrt{(1/n_1 + 1/n_2)s^2}. \quad (7)$$

For the null hypothesis  $H_0: \delta = 0$ , we have  $t = 1.63599$  with 5 degrees of freedom. The resulting two-tailed  $p$  value is .16277 with a 95% confidence interval of  $[-12.64209, 2.80875]$  or  $-12.64209 \leq \delta \leq 2.80875$ . The result is that the difference between the two means is not significant at the .05 alpha level.

When it is not reasonable to assume  $\sigma_1^2 = \sigma_2^2$ , neither a pivotal statistic nor an exact confidence interval procedure exist. One simple way to solve this problem, however, is to use a proxy

$$t^* = \frac{\delta - (\bar{x}_2 - \bar{x}_1)}{\sqrt{s_1^2/n_1 + s_2^2/n_2}} \sim t[\min(\nu_1, \nu_2)], \quad (8)$$

where  $\nu_1 = n_1 - 1$  and  $\nu_2 = n_2 - 1$ . Restate in terms of a confidence interval, we have

$$\bar{x}_2 - \bar{x}_1 \pm t_{\alpha/2}[\min(\nu_1, \nu_2)] \sqrt{s_1^2/n_1 + s_2^2/n_2}. \quad (9)$$

Note, in this case (i.e.,  $t^*$  test), the actual confidence is greater than  $100(1 - \alpha)\%$  (Mickey & Brown, 1966). The Marascuilo and Serlin (1988) data yield  $t^* = 1.50493$ ; with 2 degrees of freedom, the resulting two-tailed  $p$  value is .27127. The 95% confidence interval is  $[-18.97365, 9.14031]$ . When  $n_1 = n_2 = n$ , the value obtained from Equation 4 is the same as that from Equation 8. In this special case we can use Equations 4 and 7 to test the null hypothesis and to obtain the  $100(1 - \alpha)\%$  confidence interval, respectively. However, as noted in Hsu (1938) and Robinson (1976), the Type I error rate might be greater than the specified nominal level unless the equality of two variances is satisfied.

The above  $t^*$  solution is a simple ad hoc approach to the Behrens-Fisher problem. Two other approaches based on the test statistic  $t^*$  are derived from fiducial theory and Bayesian theory. We first present a solution from fiducial theory followed by a solution based on the Bayesian approach.

### Fisher's Fiducial Approach

Fisher (1935) proposed a statistical method for obtaining a probability distribution of a parameter from observed data called a fiducial probability distribution (see Fraser, 1978 for

a brief review). Recall that we assume the two sets of observations are random samples drawn from independent normal distributions. The quantities  $\bar{x}_i$  and  $s_i^2$  are jointly sufficient for  $\mu_i$  and  $\sigma_i^2$  having independent sampling distributions  $N(\mu_i, \sigma_i^2/n_i)$  and  $(\sigma_i^2/\nu_i)\chi_{\nu_i}^2$ , respectively, for  $i = 1, 2$ . Consequently, we can define

$$t_i = \frac{\mu_i - \bar{x}_i}{\sqrt{s_i^2/n_i}} \sim t(n_i - 1). \quad (10)$$

By logical inversion

$$\mu_i = \bar{x}_i + t_i \sqrt{s_i^2/n_i} \quad (11)$$

and  $\delta = \mu_2 - \mu_1$  is distributed as

$$\delta = \bar{x}_2 - \bar{x}_1 + t_2 \sqrt{s_2^2/n_2} - t_1 \sqrt{s_1^2/n_1}. \quad (12)$$

The fiducial distribution of  $\delta$  can be used to make fiducial inferences about  $\delta$  and to set fiducial intervals. Instead of obtaining the distribution of  $\delta$ , for the purpose of tabulation, however, Fisher (1935, 1939) chose the statistic

$$\tau = \frac{\delta - (\bar{x}_2 - \bar{x}_1)}{\sqrt{s_1^2/n_1 + s_2^2/n_2}} = t_2 \cos \theta - t_1 \sin \theta, \quad (13)$$

where  $\theta$  is taken in the first quadrant and

$$\tan \theta = \frac{s_1/\sqrt{n_1}}{s_2/\sqrt{n_2}}. \quad (14)$$

Noted that  $\tau$  is the same quantity as  $t^*$  but for ease of presentation in the context of both fiducial and Bayesian theories we use  $\tau$ . The distribution of  $\tau$  is the Behrens-Fisher distribution and is defined by the three parameters  $\nu_1$ ,  $\nu_2$ , and  $\theta$ ,  $\tau = \tau(\nu_1, \nu_2, \theta)$ . The distribution can be seen as a mixture of two  $t$  distributions,  $t(\nu_1)$  and  $t(\nu_2)$ .

If we denote  $\tau_{\alpha/2}(\nu_1, \nu_2, \theta)$  as the value for which

$$\Pr\{\tau > \tau_{\alpha/2}(\nu_1, \nu_2, \theta)\} = \alpha/2. \quad (15)$$

then the  $100(1 - \alpha)\%$  fiducial interval is

$$\bar{x}_2 - \bar{x}_1 \pm \tau_{\alpha/2}(\nu_1, \nu_2, \theta) \sqrt{s_1^2/n_1 + s_2^2/n_2}. \quad (16)$$

## Bayesian Approach

In this section, we present the Bayesian approach to the Behrens-Fisher problem given by Jeffreys (1940, 1961). This solution is equivalent to that obtained via the fiducial inference approach. From the fundamental theorem of the normal distribution, the quantities  $\bar{x}_i$  and  $s_i^2$  are jointly sufficient for  $\mu_i$  and  $\sigma_i^2$ , which have independent sampling distributions  $N(\mu_i, \sigma_i^2/n_i)$  and  $(\sigma_i^2/\nu_i)\chi_{\nu_i}^2$  for  $i = 1, 2$ . Then, assuming vague reference prior distributions for  $\mu_1$ ,  $\mu_2$ ,  $\log \sigma_1$ , and  $\log \sigma_2$  (i.e., independent and locally uniform), it can be shown that the joint posterior distribution of  $\mu_1$  and  $\mu_2$  is

$$p(\mu_1, \mu_2 | x) = p(\mu_1 | \bar{x}_1, s_1^2) p(\mu_2 | \bar{x}_2, s_2^2), \quad (17)$$

where  $x = (x_1, x_2)$  and for  $i = 1, 2$ ,

$$p(\mu_i | \bar{x}_i, s_i^2) = \frac{(s_i / \sqrt{n_i})^{-1}}{B(\frac{1}{2}, \frac{\nu_i}{2}) \sqrt{\nu_i}} \left[ 1 + \frac{n_i(\mu_i - \bar{x}_i)^2}{\nu_i s_i^2} \right]^{-(\nu_i+1)/2}, \quad -\infty < \mu_i < \infty. \quad (18)$$

where  $B(p, q)$  is the beta function,  $B(p, q) = \Gamma(p)\Gamma(q)/\Gamma(p+q)$ . Hence, a posteriori  $\mu_1$  and  $\mu_2$  are independent and distributed as scaled  $t$  distributions,  $t(\bar{x}_1, s_1^2/n_1, \nu_1)$  and  $t(\bar{x}_2, s_2^2/n_2, \nu_2)$ , respectively.

In order to obtain the posterior distribution of  $\delta = \mu_2 - \mu_1$ , we transform  $\delta = \mu_2 - \mu_1$  and  $\delta_1 = \mu_1$  and then integrate out  $\delta_1$  from the joint distribution of  $\delta$  and  $\delta_1$ :

$$p(\delta | x) = \int p(\delta, \delta_1 | x) d\delta_1, \quad -\infty < \delta < \infty. \quad (19)$$

Since the transformation has unit Jacobian, it follows that

$$p(\delta | \bar{x}_1, s_1^2, \bar{x}_2, s_2^2) = k \int_{-\infty}^{\infty} \left[ 1 + \frac{n_1(\delta_1 - \bar{x}_1)^2}{\nu_1 s_1^2} \right]^{-(\nu_1+1)/2} \left[ 1 + \frac{n_2(\delta + \delta_1 - \bar{x}_2)^2}{\nu_2 s_2^2} \right]^{-(\nu_2+1)/2} d\delta_1, \quad (20)$$

where

$$k = \frac{(s_1 / \sqrt{n_1})^{-1} (s_2 / \sqrt{n_2})^{-1}}{B(\frac{1}{2}, \frac{\nu_1}{2}) \sqrt{\nu_1} B(\frac{1}{2}, \frac{\nu_2}{2}) \sqrt{\nu_2}}. \quad (21)$$

The distribution of  $\delta = \mu_2 - \mu_1$  can be computed by numerical integration to any reasonable level of accuracy. We present some approximations for the distribution of  $\delta$  later for cases where  $\nu_1$  and  $\nu_2$  are relatively large.

For convenience, we use  $\tau = t_2 \cos \theta - t_1 \sin \theta$ , where, in terms of the scaled  $t$  distribution,  $t_1$  and  $t_2$  are independently distributed as  $t(0, 1, \nu_1)$  and  $t(0, 1, \nu_2)$ , respectively. The posterior distribution of  $\mu_2 - \mu_1$  and the inference about  $\delta$  can be equivalently determined from the distribution of  $\tau$ . The density function of  $\tau$  may be obtained from the joint distribution of  $t_1$  and  $t_2$  by the following integration:

$$p(\tau | \nu_1, \nu_2, \theta) = \int \int_{\tau=t_2 \cos \theta - t_1 \sin \theta} p(t_1) p(t_2) dt_1 dt_2, \quad -\infty < \tau < \infty, \quad (22)$$

where

$$p(t_i) = \frac{1}{B(\frac{1}{2}, \frac{\nu_i}{2}) \sqrt{\nu_i}} \left( 1 + \frac{t_i^2}{\nu_i} \right)^{-(\nu_i+1)/2}, \quad i = 1, 2. \quad (23)$$

To integrate, we set  $\tau = t_2 \cos \theta + t_1 \sin \theta$  and  $\zeta = t_2 \sin \theta + t_1 \cos \theta$ . Since the resulting transformation has unit Jacobian,

$$p(\tau | \nu_1, \nu_2, \theta) = k' \int_{-\infty}^{\infty} \left[ 1 + \frac{(\zeta \cos \theta - \tau \sin \theta)^2}{\nu_1} \right]^{-(\nu_1+1)/2} \left[ 1 + \frac{(\zeta \sin \theta + \tau \cos \theta)^2}{\nu_2} \right]^{-(\nu_2+1)/2} d\zeta, \quad (24)$$

where

$$k' = \frac{1}{B(\frac{1}{2}, \frac{\nu_1}{2}) \sqrt{\nu_1} B(\frac{1}{2}, \frac{\nu_2}{2}) \sqrt{\nu_2}}. \quad (25)$$

The distribution of  $\tau$  depends only on three parameters  $\nu_1$ ,  $\nu_2$ , and  $\theta$ , a result identical to the case given by Fisher (1935, 1939) using fiducial theory. The distribution of  $\tau$  (i.e., Behrens-Fisher distribution) is a symmetric distribution, similar to the  $t$  distribution in appearance. Since Bayesian highest posterior density (HPD) intervals are numerically identical with Fisher's fiducial intervals, they can be obtained using tables such as Sukhatme (1938).

#### Tables of the Behrens-Fisher Distribution

A number of tables have been presented for the Behrens-Fisher distribution beginning with Sukhatme (1938) and Sukhatme et al. (1951). Subsequently, Fisher and Yates (1957, Tables 6 and 6-1) presented significance points of the Behrens-Fisher distribution for  $\nu_1, \nu_2 = 6, 8, 12, 24, \infty$ ,  $\theta = 0^\circ (15^\circ) 90^\circ$ ,  $\alpha = .05, .01$  and  $\nu_1 \geq \nu_2 = 1(2)7$ ,  $\theta = 0^\circ (15^\circ) 90^\circ$ ,  $\alpha = .10, .05, .02, .01$ . Weir (1966) presented percentage points of the Behrens-Fisher distribution for  $\nu_1, \nu_2 = 6, 8, 12, 24, \infty$ ,  $\theta = 0^\circ (15^\circ) 90^\circ$ ,  $\alpha = .001$ . Table 41 in Issacs et al.

(1974) contains Behrens-Fisher percentage points for  $\nu_1, \nu_2 = 6, 8, 12, 24, \infty$ ,  $\theta = 0^\circ(15^\circ)45^\circ$ ,  $\alpha = .50, .20, .10, .05, .02$ . Lindley and Scott (1984, Tables 11-a and 11-b) provide tables for the Behrens-Fisher distribution for  $\nu_1 \geq \nu_2 = 1(1)8, 10, 12, 24, \infty$ ,  $\theta = 0^\circ(15^\circ)90^\circ$ ,  $\alpha = .05, .01$ . Tables of percentage points of the Behrens-Fisher distribution are also reproduced in Finney (1952), Lee (1989), and Novick and Jackson (1974) (see also Greenwood & Hartley, 1962; Johnson, Kotz, & Balakrishnan, 1995). No tables are yet available, however, when the degrees of freedom for  $\nu_1$  and  $\nu_2$  are small and even for  $\alpha = .10, .02$ .

The purpose of this section is to explain the method of approximation used in the computer program for the percentage points of the Behrens-Fisher distribution and to present a table of percentage points for  $\nu_1, \nu_2 = 1(1)8, 10, 12, 24, \infty$ ,  $\theta = 0^\circ(15^\circ)90^\circ$ ,  $\alpha = .10, .05, .02, .01$ . The method is based on Sukhatme (1938). The complete tables of the Behrens-Fisher distribution for  $\nu_1, \nu_2 = 1(1)30, \infty$ ,  $\theta = 0^\circ(15^\circ)90^\circ$ ,  $\alpha = .10, .05, .02, .01$  are available from the authors. In addition, two computer programs, B and BF, which can be used to obtain tail areas and percentage values of the Behrens-Fisher distribution are available from the authors.

The probability that  $\tau$  exceeds  $\tau_0$  can be written as

$$\Pr\{\tau > \tau_0\} = \int_{\tau_0}^{\infty} p(\tau | \nu_1, \nu_2, \theta) d\tau, \quad (26)$$

where  $p(\tau | \nu_1, \nu_2, \theta)$  is given in Equation 24. Transforming  $t_1 = \zeta \cos \theta - \tau \sin \theta$  and  $t_2 = \zeta \sin \theta + \tau \cos \theta$ , and changing the order of integration, it follows that

$$\Pr\{\tau > \tau_0\} = \int_{-\infty}^{\infty} p(t_1) \int_{t_0}^{\infty} p(t_2) dt_2 dt_1, \quad (27)$$

where  $t_0 = \tau_0 / \cos \theta + t_1 \tan \theta$  and  $p(t_i)$  is defined in Equation 23. Next, if we define

$$f(t_1) = p(t_1) \int_{t_0}^{\infty} p(t_2) dt_2 = p(t_1) \Pr\{t_2 > t_0\}, \quad (28)$$

then

$$\Pr\{\tau > \tau_0\} = \int_{-\infty}^{\infty} f(t_1) dt_1 = \lim_{n \rightarrow \infty} \sum_{k=1}^n f(c_k) \Delta t_1 \approx \sum_{k=1}^n f(c_k) \Delta t_1. \quad (29)$$

As  $c \rightarrow \pm\infty$ ,  $f(c) \rightarrow 0$  and  $f$  is a nonnegative continuous function. The integral can be approximated via numerical integration to any reasonable degree of accuracy. In the computer programs we set  $\Delta t_1 = 10^{-1}$  and define  $c_1$  as the largest number with one decimal

place, where both  $c_1 < 0$  and  $f(c_1)\Delta t_1 \geq 10^{-15}$  [i.e.,  $f(c_1) \geq 10^{-14}$ ], and  $c_n$  as the smallest number with one decimal place where both  $c_n > 0$  and  $f(c_n)\Delta t_1 \geq 10^{-15}$  [i.e.,  $f(c_n) \geq 10^{-14}$ ].

Following Box and Tiao (1973), the integration process can be viewed geometrically in Figure 1. In the figure, the joint distribution of  $t_1$  and  $t_2$ , [i.e., the product  $p(t_1)p(t_2)$ ], is illustrated by the three dimensional plot. Also shown is the distribution of  $\tau$ . For a given  $\tau_0$ , the equation  $\tau_0 = t_2 \cos \theta - t_1 \sin \theta$  determines a line on the two dimensional  $t_1t_2$ -plane.  $\Pr\{\tau > \tau_0\}$  can be obtained by aggregating  $\Pr\{t_2 > t_0\}$  weighted by  $p(t_1)$ .

---

---

To illustrate the method, let us suppose that we want to calculate the tail area of  $\tau_0 = 1.99704$  for  $\nu_1 = \nu_2 = 60$  and  $\theta = 45^\circ$ . The computer program B first calculates  $c_1$  using temporary values of  $t_1$ . If  $t_1 = -10.4$ , then  $f(-10.4) < 10^{-15}$  and, consequently,  $c_1 = -10.3$ . Similarly with  $\Delta t_1 = 10^{-1}$ , we obtain  $c_n = 4.5$ . Values of  $t_1$ , values of  $t_0$  corresponding to  $\tau_0 = 1.99704$ ,  $\Pr\{t_2 > t_0\}$ , and values of  $f(c_k)\Delta t_1$  are given in Table 1. The probability that  $\tau$  exceeds  $\tau_0$  is .025. Executing B requires input values for  $\tau_0$ ,  $\nu_1$ ,  $\nu_2$ ,  $\theta$ .

---

Insert Table 1 about here

---

The computer program BF can be used to obtain percentage values of  $\tau$ . To obtain percentage points, the program requires input for  $\nu_1$ ,  $\nu_2$ ,  $\theta$ ,  $\alpha$ , where

$$\alpha = \Pr\{\tau < -\tau_{\alpha/2}(\nu_1, \nu_2, \theta)\} + \Pr\{\tau > \tau_{\alpha/2}(\nu_1, \nu_2, \theta)\}. \quad (30)$$

The  $100(1 - \alpha)\%$  HPD interval, which is in fact the same as the fiducial interval, can be constructed from a single run of the computer program BF. The  $100(1 - \alpha)\%$  HPD interval for  $\delta$  is given in Equation 16. Table 2 contains the percentage points of the Behrens-Fisher distribution for  $\nu_1, \nu_2 = 1(1)8, 10, 12, 24, \infty$ ,  $\theta = 0^\circ(15^\circ)90^\circ$ ,  $\alpha = .10, .05, .02, .01$ .

For the Marascuilo and Serlin (1988) data,  $\tau_0 = 1.50493$ ,  $\nu_1 = 3$ ,  $\nu_2 = 2$ ,  $\theta = 27.19365$ . From the computer program B, we obtain  $\Pr\{\tau > \tau_0\} = .14546$ , indicating the difference between the two means is not significant at  $\alpha = .05$ . From the computer program BF, we obtain  $\tau_{.025}(3, 2, 27.19365) = 4.13069$ . The corresponding 95% HPD interval is  $[-18.41183, 8.57850]$ .

### Approximation of the Posterior Distribution

Since the Behrens-Fisher distribution has no simple form, approximations have been used to obtain percentage points (e.g., Barnard, 1984; Banerjee, 1960, 1961; Cochran, 1964; Cochran & Cox, 1950; Fisher, 1941; Ghosh, 1975; Linssen, 1991; Patil, 1965; Rahman & Saleh, 1974). For example, Banerjee (1960, 1961) proposed the approximation

$$\tau_{\alpha/2}^B = \sqrt{t_{\alpha/2}^2(\nu_1)c + t_{\alpha/2}^2(\nu_2)(1 - c)}, \quad (31)$$

where

$$c = \frac{s_1^2/n_1}{s_1^2/n_1 + s_2^2/n_2} = \sin^2 \theta \quad (32)$$

and, consequently,

$$1 - c = \frac{s_2^2/n_2}{s_1^2/n_1 + s_2^2/n_2} = \cos^2 \theta. \quad (33)$$

Cochran and Cox (1950) proposed

$$\tau_{\alpha/2}^{CC} = t_{\alpha/2}(\nu_1)c + t_{\alpha/2}(\nu_2)(1 - c). \quad (34)$$

Reporting the statement of a  $p$  value, whether or not it is followed by a pronouncement concerning the significance of the result, may sometimes be more informative than reporting a fixed-level hypothesis testing result. In the context of Bayesian inference, it is desirable to show the whole posterior distribution rather than particular intervals. The posterior distribution of  $\delta$  can be obtained by numerical integration of Equation 19 or using formulas presented by Ghosh (1975). All methods for the approximations of the percentage points of the Behrens-Fisher distribution can be used to plot the approximate posterior distribution.

One important point may be that neither the numerical integration using Equation 19 nor Ghosh's method expresses the posterior distribution in terms of tabled functions. To do

so, we can use Patil's (1965) approximation or Molenaar's (1979) methods. For example, Patil's (1965) method fits the  $t$  distribution to the distribution of  $\tau$  by equating the second and the fourth moments. Patil noted that the formula is valid for  $\nu_1, \nu_2 \geq 5$  and works quite well for  $\nu_1, \nu_2 \geq 7$ . It can be shown that  $\tau$  is approximately distributed as

$$\tau = \frac{t(g)}{h}, \quad (35)$$

where

$$g = 4 + \left( \frac{\nu_2 \cos^2 \theta}{\nu_2 - 2} + \frac{\nu_1 \sin^2 \theta}{\nu_1 - 2} \right)^2 \left[ \frac{\nu_2^2 \cos^4 \theta}{(\nu_2 - 2)^2 (\nu_2 - 4)} + \frac{\nu_1^2 \sin^4 \theta}{(\nu_1 - 2)^2 (\nu_1 - 4)} \right]^{-1} \quad (36)$$

and

$$h^2 = \frac{g}{g - 2} \left( \frac{\nu_2 \cos^2 \theta}{\nu_2 - 2} + \frac{\nu_1 \sin^2 \theta}{\nu_1 - 2} \right)^{-1}. \quad (37)$$

In terms of the scaled  $t$  distribution,  $\tau$  is approximately distributed as  $t(0, h^{-2}, g)$ . Consequently, the difference of the mean values  $\delta = \mu_2 - \mu_1$  is distributed a posteriori as  $t[\bar{x}_2 - \bar{x}_1, (s_1^2/n_1 + s_2^2/n_2)/h^2, g]$ . Patil's approximation (or Molenaar's methods) cannot be used on the data from Marascuilo and Serlin (1988) due to the small degrees of freedom. We can use Ghosh's (1975) method, however, although neither approximation is better than the numerical integration method. The posterior distribution of  $\delta$  obtained from the numerical integration method is presented in Figure 2. The posterior distribution of  $\delta$ ,  $p(\delta|\mathbf{x})$ , is centered at  $\bar{x}_2 - \bar{x}_1 = 4.91667$ . The 95% HPD interval  $[-18.41183, 8.57850]$  is also presented in Figure 2.

### Hypothesis Testing Based on Lindley

Lindley (1965) suggested a simple test of a point null hypothesis, for example.  $H_0: \delta = \delta_0$  against  $H_1: \delta \neq \delta_0$  under a vague or diffuse prior. To conduct a significance test at level  $\alpha$ , Lindley suggests finding a  $100(1 - \alpha)\%$  HPD region.  $H_0$  is rejected only if  $\delta_0$  is outside of this region. Notice that a directional hypothesis test can also be easily accommodated. Berger (1985) and Lee (1989) contain other Bayesian approaches to hypothesis testing.

In the Bayesian context, it is often more useful to obtain the whole posterior distribution. The 95% HPD interval in Figure 2 contains 0 and the null hypothesis  $H_0: \delta = 0$  cannot be rejected.

### Frequentist Approach

Other solutions to the Behrens-Fisher problem also exist (e.g., Aspin, 1948, 1949; Gronow, 1951; James, 1959; Lee & Gurland, 1975; Mehta & Srinivasan, 1970; Nel, van der Merwe, & Moser, 1990; Pagurova, 1968; Scheffé, 1943; Sprott & Farewell, 1993; Tsui & Weerahandi, 1989; Wald, 1955; Welch, 1938, 1947). Several solutions to the Behrens-Fisher problem have been investigated on the basis of their size and magnitude of their power (e.g.. Davenport & Webster, 1975; Lee & Gurland, 1975; Mehta & Srinivasan, 1970; Wang, 1971). Of all those methods, perhaps those due to Welch (1938, 1947), Aspin (1948, 1949), and Tsui and Weerahandi (1989) are the most important from the frequentist perspective.

Welch (1938) presented an approximation of  $t^*$  by the method of moments and later (Welch, 1947) used asymptotic series expansions to obtain a critical value for terms of order  $1/\nu_i^2$ :

$$t_{\alpha/2}^W(\nu_1, \nu_2, c) = z_{\alpha/2} (1 + V_1 + V_2), \quad (38)$$

where  $z_{\alpha/2}$  is the  $\alpha/2$  point of the standard normal distribution (i.e., the probability of exceeding  $z_{\alpha/2}$  is  $\alpha/2$ ) and

$$V_1 = \left( \frac{1 + z_{\alpha/2}^2}{4} \right) V_{21}, \quad (39)$$

and

$$V_2 = - \left( \frac{1 + z_{\alpha/2}^2}{2} \right) V_{22} + \left( \frac{3 + 5z_{\alpha/2}^2 + z_{\alpha/2}^4}{3} \right) V_{32} - \left( \frac{15 + 32z_{\alpha/2}^2 + 9z_{\alpha/2}^4}{32} \right) V_{21}^2, \quad (40)$$

where  $c$  is given in Equation 32 and

$$V_{ru} = \frac{c^r}{\nu_1^u} + \frac{(1-c)^r}{\nu_2^u}. \quad (41)$$

The result was extended further by Aspin (1948) to terms of order  $1/\nu_i^3$  and  $1/\nu_i^4$  and the latter has become known as the Welch-Aspin test:

$$t_{\alpha/2}^{WA}(\nu_1, \nu_2, c) = z_{\alpha/2} (1 + V_1 + V_2 + V_3 + V_4), \quad (42)$$

where  $V_3$  and  $V_4$  are defined in Aspin's (1948, p. 90) Equations 13 and 14, respectively. Lee and Gurland (1975) noted that Aspin's Equation 14 contained an error: Specifically, that  $V_{42}$  should be  $V_{22}$ . The Welch-Aspin test rejects the null hypothesis  $H_0$  at level  $\alpha$  when  $t^* > t_{\alpha/2}^{WA}(\nu_1, \nu_2, c)$ . We can also obtain the  $100(1 - \alpha)\%$  confidence interval as

$$\bar{x}_2 - \bar{x}_1 \pm t_{\alpha/2}^{WA}(\nu_1, \nu_2, c) \sqrt{s_1^2/n_1 + s_2^2/n_2}. \quad (43)$$

Aspin (1949) presented tables of critical values of the Welch-Aspin test for  $\nu_1, \nu_2 = 6, 8, 10, 15, 20, \infty, c = 0(.1)1, \alpha = .10$  and  $\nu_1, \nu_2 = 10, 12, 15, 20, 30, \infty, c = 0(.1)1, \alpha = .02$ . Trickett, Welch, and James (1956) presented tables for  $\nu_1, \nu_2 = 8, 10, 12, 15, 20, \infty, c = 0(.1)1, \alpha = .05$  and  $\nu_1, \nu_2 = 10, 12, 15, 20, 30, \infty, c = 0(.1)1, \alpha = .01$ . Pearson and Hartley (1970, Table 11) reproduced Aspin (1949) and Trickett et al. (1956). Note that critical values for certain small sample sizes (e.g.,  $\nu_i < 6$ ) are not available from these tables.

In addition Welch (1938) suggested another method based on a random number of degrees of freedom. This is often referred to as the approximate degrees of freedom solution or Welch's approximate  $t$  test. In this regard Welch (1938) presented the following critical value:

$$t_{\alpha/2}^{Wt} = t_{\alpha/2} \left[ \nu' = \frac{1}{c^2/\nu_1 + (1-c)^2/\nu_2} \right], \quad (44)$$

where the degrees freedom  $\nu'$  is in general not an integer. The critical value  $t_{\alpha/2}^{\nu'}$  can be obtained using the computer program ET (Galen Research, 1992). When using the  $t$  table it is customary to round  $\nu'$  down to the nearest integer although the impact of such rounding has not been investigated. It is of interest to note that the equivalent of Welch's approximate  $t$  test had been proposed by Smith (1936) in a somewhat different context for a related problem (see also Cochran, 1964; Satterthwaite, 1941, 1946; Wallace, 1980). Wang (1971) indicated that Welch's approximate  $t$  test is not as effective as the Welch-Aspin test. Even so Best and Rayner (1987), Davenport and Webster (1975), and Scheffé (1970) indicated that Welch's approximate  $t$  test may be the best practical solution.

For the Marascuilo and Serlin (1988) data  $t^* = 15.0493$  and the critical values are  $t_{.025}^W = 3.20703$  and  $t_{.025}^{Wt} = t_{.025}(3.05344) = 3.15117$ . The corresponding 95% confidence intervals of the Welch test of order  $1/\nu_i^2$  and Welch's approximate  $t$  test are  $[-15.39420, 5.56086]$  and  $[-15.21169, 5.37835]$ , respectively.

For the significance testing of one-sided hypotheses, for example,  $H_0: \delta \leq \delta_0$  versus  $H_1: \delta > \delta_0$ , Tsui and Weerahandi (1989) suggested use of generalized extreme regions of the form

$$R_x(\delta, \eta) = \{X : T(X; x, \delta, \eta) \geq T(x; x, \delta, \eta)\}, \quad (45)$$

where  $x$  denotes the observed data for the random variable  $X$ ,  $T(X; x, \delta, \eta)$  is a test statistic that is stochastically increasing in  $\delta$ , and  $\eta$  is the nuisance parameter. The generalized  $p$ -value is defined as

$$p = \sup_{\delta \leq \delta_0} \Pr \{X \in R_x(\delta, \eta)\} \quad (46)$$

and it is free of the nuisance parameter  $\eta$ . A small value of  $p$  suggests that the observed  $x$  does not support  $H_0$ .

In the context of the Behrens-Fisher problem we use the following notations of random variables as  $X_i = (X_{i1}, \dots, X_{in_i})$ ,  $\bar{X}_i \sim N(\mu_i, \sigma_i^2/n_i)$ , and  $\nu_i S_i^2/\sigma_i^2 \sim \chi^2(\nu_i)$ , for  $i = 1, 2$ . Define  $x_i$ ,  $\bar{x}_i$ , and  $s_i^2$  as the observed values of  $X_i$ ,  $\bar{X}_i$  and  $S_i^2$ , respectively. Note that the parameter of interest is  $\delta = \mu_2 - \mu_1$  and that the nuisance parameter  $\eta$  contains both  $\sigma_1^2$  and  $\sigma_2^2$ . In place of  $T(X; x, \delta, \eta)$ , Tsui and Weerahandi (1989) considered a generalized test variable

$$W(X) = W(X_1, X_2; x_1, x_2, \sigma_1^2, \sigma_2^2) = (\bar{X}_2 - \bar{X}_1) \left( \frac{\sigma_1^2}{n_1} + \frac{\sigma_2^2}{n_2} \right)^{-1/2} \left( \frac{\sigma_1^2 s_1^2}{n_1 S_1^2} + \frac{\sigma_2^2 s_2^2}{n_2 S_2^2} \right)^{1/2} \quad (47)$$

and hence

$$W(x) = W(x_1, x_2; x_1, x_2, \sigma_1^2, \sigma_2^2) = \bar{x}_2 - \bar{x}_1. \quad (48)$$

The distribution of  $W$  given  $x_1$ , and  $x_2$  is free of the nuisance parameter and can be seen as  $Z(s_1^2/U + s_2^2/V)^{1/2}$ , where  $Z$ ,  $U$ , and  $V$  are independent,  $Z \sim N(\delta, 1)$ ,  $U \sim \chi^2(\nu_1)$ , and  $V \sim \chi^2(\nu_2)$ . In addition, the family of cumulative distributions of  $W(X)$  for given  $x_1$  and  $x_2$  is stochastically increasing in  $\delta$  (Lehmann, 1986). The generalized extreme regions can be defined as

$$R_{x_1, x_2}(\delta, \sigma_1^2, \sigma_2^2) = \{(X_1, X_2) : W(X) - W(x) \geq 0\} \quad (49)$$

and the generalized  $p$  value is

$$p = \Pr \{W(X) \geq W(x) | \delta = 0\} = \Pr \left\{ Y(\nu_1 + \nu_2)^{-1/2} \left( \frac{\nu_1 s_1^2}{n_1 C} + \frac{\nu_2 s_2^2}{n_2(1-C)} \right)^{1/2} \geq \bar{x}_2 - \bar{x}_1 \right\} \quad (50)$$

$$= E \left\{ \Psi \left[ (\bar{x}_1 - \bar{x}_2) \left( \frac{\nu_1 s_1^2}{n_1 C} + \frac{\nu_2 s_2^2}{n_2(1-C)} \right)^{-1/2} (\nu_1 + \nu_2)^{1/2} \right] \right\}, \quad (51)$$

where  $Y$  and  $C$  are independent,  $Y = Z [(U + V)/(\nu_1 + \nu_2)]^{-1/2}$  has a form of Student's  $t$  distribution with  $\nu_1 + \nu_2$  degrees of freedom,  $C = U/(U + V) \sim \text{beta}(\nu_1/2, \nu_2/2)$ , and  $\Psi(\cdot)$  is the cumulative density function of Student's  $t$  distribution with  $\nu_1 + \nu_2$  degrees of freedom. The expectation  $E$  is performed with respect to  $C$ . Equation 51 can be written as

$$\int_0^1 \Pr \{ t(\nu_1 + \nu_2) \leq \tau_0 \phi(C) | C \} \frac{1}{B(\frac{\nu_1}{2}, \frac{\nu_2}{2})} C^{(\nu_1/2)-1} (1-C)^{(\nu_2/2)-1} dC, \quad (52)$$

where

$$\tau_0 = \frac{(x_1 - x_2)}{\sqrt{s_1^2/n_1 + s_2^2/n_2}} \quad (53)$$

and

$$\phi(C) = \left[ \frac{(\nu_1 + \nu_2)C(1-C)}{\nu_1(1-C)\sin^2 \theta + \nu_1 C \cos^2 \theta} \right]^{1/2}. \quad (54)$$

Equation 52 is, in fact, the same as  $\Pr\{\tau \leq \tau_0\} = 1 - \Pr\{\tau > \tau_0\}$ , where  $\Pr\{\tau > \tau_0\}$  is defined in Equation 26 (cf. Ruben, 1960). For  $H_0: \delta \leq 0$  with  $\delta = \mu_2 - \mu_1$ , we obtained  $\Pr\{\tau \leq \tau_0\} = .85454$  from the computer program B. The data do not support the null hypothesis. If we use a different  $\delta$  (e.g.,  $\delta = \mu_1 - \mu_2$ ), however, we have

$$p = \int_0^1 \Pr \{ t(\nu_1 + \nu_2) \geq \tau_0 \phi(C) | C \} \frac{1}{B(\frac{\nu_1}{2}, \frac{\nu_2}{2})} C^{(\nu_1/2)-1} (1-C)^{(\nu_2/2)-1} dC \quad (55)$$

and Equation 55 and Equation 26 are numerically identical.

### Summary

The Behrens-Fisher problem has been one of the focal points of the controversy between the Neyman-Pearson frequentist and Fisherian approaches (as well as possibly the Bayesian approach) to significance testing and statistical inference (for further discussion, see Bartlett, 1936; Fisher, 1956; Lehmann, 1993; Wallace, 1980; Welch, 1956). Although substantial agreement can be found among the results from the various methods, there is also substantial disagreement among proponents of various positions.

Table 3 summarizes the critical values and the 95% confidence/HPD intervals for the data from Marascuilo and Serlin (1988) used to illustrate these methods. The conservative

$t^*$  test yielded the largest critical value and, consequently, the widest confidence interval. The  $t$  test yielded the smallest critical value and the shortest confidence interval. All other confidence/HPD intervals lie between the two intervals (see also Mickey & Brown, 1966). Under the assumption that  $\sigma_1^2 = \sigma_2^2$ , the confidence interval of Equation 7, which is a frequentist solution, coincides with the fiducial interval and as well as with a Bayesian HPD interval based on the vague reference prior. For directional hypothesis testing, the frequentist solution by Tsui and Weerahandi's (1988) yields the same conclusion as fiducial and Bayesian approaches.

---

From the Neyman-Pearson approach, efforts continue to construct or approximate a similar test for which the control of Type I error holds for all  $\sigma_i^2, i = 1, 2$ . Linnik (1968/1966) proved, however, that a uniformly most powerful test does not exist in the context of the Behrens-Fisher problem. As indicated in Lehmann (1993) and Wallace (1980), the main difference between the Bayesian (or Fisher) and Neyman-Pearson approaches is whether or not the inference is conditioned.

Bayesian inference is conditional depending on unknown nuisance parameters. The Bayesian context discussed in this paper was only for the noninformative prior. In the general Bayesian context in which informative priors may be used, the attempt is made to incorporate the prior information. If one has substantial prior information about the parameters, especially information which can be approximated by independent normal and chi-square distributions for  $\mu_i$  and  $\sigma_i^2$ , respectively, then the Behrens-Fisher problem can be extended to incorporate it. Other Bayesian methods for the Behrens-Fisher problem have also been presented by Broemeling, Son, and Hamdy (1990), Dayal and Dickey (1976), Johnson and Weerahandi (1988), and Patil (1964).

When there are more than two groups, the Behrens-Fisher problem becomes the generalized Behrens-Fisher problem. When more than one variable is of interest, the Behrens-Fisher problem becomes a multivariate one. Procedures for the generalized Behrens-Fisher problem have been proposed by James (1951), Johansen (1980), Welch (1951), Tamhane (1977), and Tsakok (1978). Comparisons of the solutions and the corresponding robustness

problem for general linear hypotheses is treated by Brown and Forsythe (1974) and Clinch and Kesselman (1982). The multivariate Behrens-Fisher problem in which two groups and two or more variables are of concern is discussed by Bennett (1980), Dalai (1978), Dalal and Fortini (1983), James (1954), Johnson and Weerahandi (1988), Kim (1992), Siotani (1987), Subrahmaniam and Subrahmaniam (1973, 1975), and Yao (1965).

In this review, we have focused on parametric solutions to the Behrens-Fisher problem. Nonparametric or distribution-free solutions have also been proposed for this type of problem (see Lehmann, 1975). In general, these methods attempt to evaluate the strength of the information in the data by replacing observed values with ranks or using permutations of the data.

The Behrens-Fisher problem itself is concerned with only one of the assumptions of the *t* test (or the analysis of variance), namely, equality of variances. Other assumptions are also important for comparison of group means. Specifically, assumptions concerned with the model, independence, and normality need to be considered in addition to the equal variance assumption.

Table 3  
 Critical Values and the 95% Confidence/HPD Intervals for  
 the Marascuilo and Serlin (1988) Data

Method	Critical Value	Interval
$t^*$ Test	$4.30265 = t_{.025}(2)$	$[-18.97365, 9.14031]$
Bayesian/Fiducial	$4.13069 = \tau_{.025}(3, 2, 27.19365)$	$[-18.41183, 8.57850]$
Welch (order $1/\nu_i^2$ )	$3.20703 = t_{.025}^W(3, 2, 0.20885)$	$[-15.39420, 5.56086]$
Welch's Approximate $t$	$3.15117 = t_{.025}(3.05344)$	$[-15.21169, 5.37835]$
Student's $t$	$2.57058 = t_{.025}(5)$	$[-12.64209, 2.80875]$
